

Sander Geophysics Explores the Antarctic

Sander Geophysics Limited has earned the privilege of participating in the Antarctica's Gamburtsev Province Project (AGAP). This project is funded by the US National Science Foundation's Office of Polar Programs for the fourth International Polar Year (IPY) project in Antarctica during the 2008-2009 season. In May and June of 2007, teams from SGL and the Lamont-Doherty Earth Observatory of Columbia University installed SGL's Airborne Inertially Referenced Gravimeter (AIRGrav) in a Kenn Borek DCH-6 Twin Otter aircraft in Calgary. Once installed, the aircraft performed test flights over the Rocky Mountains and then flew to Ellesmere Island in northern Canada to test the system at extreme latitudes over the North Pole. The tests proved very successful in terms of AIRGrav data quality, noise levels, and GPS control. The success of AIRGrav during these tests led the AGAP team to select AIRGrav over other gravimeters for the demanding Antarctic survey. The Calgary tests are described in the paper "Comparison of AIRGrav and GT-1A airborne gravimeters for research applications" (Studinger, Bell and Frearson, *Geophysics Vol. 73, No.6*, November-December 2008, pp. 151-161). In May and June of 2008, teams from SGL and AGAP returned to Calgary where they installed the AIRGrav system along with the full suite of AGAP geophysical equipment in the Twin Otter. The aircraft flew a set of successful test flights over the Greenland ice sheet as a final verification of the survey platform before heading south to Antarctica for the 2008-2009 season.

The AGAP's central focus is to gather information to accurately characterize the tectonic origin of the Gamburtsev Subglacial Mountains found approximately 3 km below the million-year-old ice sheet in the deep interior of east Antarctica, as illustrated above. In addition, the project will study the relationship between these mountains and the

overlying ice sheet and subglacial lakes, and identify the location of the oldest ice to enable the recovery of the oldest climate record. The survey will take place from December 2008 to January 2009. The team from SGL that will join the AGAP team in Antarctica consists of SGL Data Processing Manager, Dr. Martin Bates, Senior Geophysicist, Stefan Elieff and Technician, Daniel Geue. SGL's AIRGrav system will collect information about the buried mountains' structure during the combined airborne gravity and magnetic survey. The Lamont-Doherty Earth Observatory of Columbia University will operate a laser altimeter that will simultaneously scan the surface of the ice during flights to provide information on surface elevation, a Synthetic Aperture Radar (SAR) that will measure ice thickness and layering in order to map the shape of the buried bedrock, and magnetometers to map the magnetic fields of the bedrock.

Sander Geophysics' AIRGrav system (shown above) offers a number of advantages over competing systems, including:

1. Significantly better resolution and accuracy
2. Ability to operate under normal daytime flying conditions
3. Ability to provide high quality gravity data while flying in drape mode
4. Ability to provide good quality aeromagnetic data concurrently with the AIRGrav data
5. Significant operational efficiencies
6. Shorter time required for data acquisition and processing

These advantages are all a result of the unique design and construction of the AIRGrav system. It accurately records and compensates for aircraft movements due to turbulence, aircraft vibrations, and drape flying, allowing for the removal of these effects from the final data during processing. Very high quality GPS, combined with SGL's proprietary GPS and gravity data processing software complete the AIRGrav system. AIRGrav system details are available on SGL's website (www.sgl.com) as well as in our technical papers.

Additional information regarding this project is available at the Lamont-Doherty Earth Observatory website for the Antarctica's Gamburtsev Province Project. <http://www.ldeo.columbia.edu/res/pi/gambit>
